Introduction

ECM® technology works as a scaffold to help rebuild missing or damaged tissue. Unlike traditional collagen dressings, ECM® is entirely natural, and is an accurate mimic of the scaffold found in healthy tissue. ECM® contains collagen, but also a range of other secondary molecules that are important for healing. Additionally, ECM® has been shown to modulate wound proteases. The aim of this case series was to clinically evaluate an advanced extracellular matrix (ECM®) technology across different Canadian care settings for the management of chronic wounds.

Methods

Thirty patients were recruited from three sites (see also population summary below). Wound types included DPUs, PU’s, skin tears, pilonidal sinus, necrotizing fasciitis, venous leg ulcers, dehisced abdominal and traumatic wound. Wound management was undertaken across various care settings, including in-patient, out-patient and home health. All wounds were managed with best practice, including debridement, maintenance of a moist wound environment and appropriate compression and off-loading. All wounds were managed with an ECM®, applied every 2-7 days to the wound bed. Wounds were visually inspected, imaged and measured over the course of management with ECM®.

Results

**Outcomes**

- **Wounds closed:** 77% (By week 12; n=23/30)
- **Average % wound size at 4 weeks:** 36% (SD=33%; range, 0% to 96%)
- **Respondents at 4 weeks:** 70% (>50% reduction in area at 4 weeks; n=21/30)

**Survival Analysis**

- **50% Respondents:** 50% (n=10/20)
- **75% Respondents:** 67% (n=15/22)
- **100% Respondents:** 50% (n=10/20)

**Case Study 1**

- **Patient:** 60 year old male
- **Medical History:** Non-insulin-dependent diabetic (Hbg A1c 7.2%), original transmetatarsal amputation in 2016.
- **Wound Description:** Diabetic foot ulcer, painful when infected otherwise has neuropathy to plantar aspect of his foot.
- **Previous Treatments:** Two courses of antibiotics, gauze dressing.

**Week 0:**
- 2.0 x 1.2 cm.
- 100% granulation tissue.
- Maceration, neuropathy.

**Week 1:**
- 1.0 x 0.9 cm.
- 100% pink granulation tissue, moisture, ECM®, GVMB®.

**Week 2:**
- 3.8 x 1.7 cm.
- Epithelialization, 100% granulation tissue. ECM®, GVMB®, foam border dressing.

**Week 5:**
- 0.8 x 0.5 cm.
- 83% wound closure.

**Case Study 2**

- **Patient:** 54 year old female.
- **Medical History:** Celiac disease, hypertension, idiopathic neutropenia.
- **Wound Description:** Post-surgical wound.
- **Previous Treatments:** Dressings, topical antibiotic, debridement, cadexomer iodine.

**Week 0:**
- 5.8 x 2.0 cm.
- 100% slough, 90% granulation tissue. ECM®, GVMB®, foam border dressing, light compression sock.

**Week 5:**
- Wound closed.

Conclusions

This represents the first Canadian evaluation of ECM® for the management of wounds. Improvements to the granulation tissue were observed and other staged chronic wounds began to resolve. Results to date are encouraging, and the availability of this advanced technology to Canadian wound specialists provides another tool for the management of these complex pathologies.
